Supranuclear Palsy (PSP), also called Stelle-Richardson-Olszewski Syndrome, reflects the combined effects of abnormal protein deposits on the brain which were often seen in people with Parkinson's. In his eponymous description of the medical condition, Dr. Richard Olszewski at the University of Rochester Medical Center in New York, noted that, due to loss of balance, patients suffering from PSP are at increased risk of falling. In addition, a person with PSP tends to have difficulty focusing their eyes and complain of blurred vision. One of the most common indicators of PSP is the loss of balance, which increases fall risk.

CORTICOBASAL DEGENERATION (CBD)

Though there are over a dozen different types of parkinsonism, one type, corticobasal degeneration (CBD), is most frequently confused with Parkinson's due to similarities in symptoms. CBD is characterized by the deterioration of multiple areas of the brain, resulting in a unique set of symptoms such as abnormalities in hand movements and gait.
